SP6691
Micro Power Boost Regulator Series White LED Driver

FEATURES
- Drives up to 6 LEDs @ 25mA
- Drives up to 8 LEDs @ 20mA
- High Output Voltage: Up to 30V
- Optimized for Single Supply, 2.7V - 4.2V Applications
- Operates Down to 1V
- High Efficiency: Greater Than 75%
- Low Quiescent Current: 20µA
- Ultra Low Shutdown Current: 10nA
- Single Battery Cell Operation
- Programmable Output Voltage
- 1Ω switch (350mV at 350mA)
- Lead Free, RoHS Compliant Packages: 8 Pin DFN, 5 pin TSOT or 5 Pin SOT23

APPLICATIONS
- White LED Driver
- High Voltage Bias
- Digital Cameras
- Cell Phone
- Battery Backup
- Handheld Computers

DESCRIPTION
The SP6691 is a micro power boost regulator that is specifically designed for powering series configuration white LED. The part utilizes fixed off time architecture and consumes only 10nA quiescent current in shutdown. Low voltage operation, down to 1V, fully utilizes maximal battery life. The SP6691 is offered in an 8 Pin DFN, 5-pin SOT-23 or 5 Pin TSOT package and enables the construction of a complete regulator occupying < 0.2 in² board space.

TYPICAL APPLICATION CIRCUIT
**ABSOLUTE MAXIMUM RATINGS**

- \( V_{\text{IN}} \) .................................................. 15V
- SW Voltage .............................................. -0.4 to 30V
- FB Voltage .................................................. 2.5V
- All other pins ................................... -0.3 to \( V_{\text{IN}} + 0.3V \)
- Current into FB ............................................. \( \pm 1mA \)
- \( T_{J} \) Max ............................................................. 125°C
- Operating Temperature Range ............ -40°C to 85°C
- Peak Output Current < 10us SW .................... 500mA
- Storage Temperature ........................... -65°C to +150°C
- Power Dissipation ......................................... 200mW
- ESD Rating ................................................. 2kV HBM

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

**ELECTRICAL CHARACTERISTICS**

Specifications are at \( T_A \) = 25°C, \( V_{\text{IN}} \) = 3.3, \( V_{\text{SHDN}} \) = \( V_{\text{IN}} \).

Operation can be best understood by referring to the functional diagram above and the typical application circuit in the front page. Q1 and Q2 along with R3 and R4 form a band gap reference. The input to this circuit completes a feedback path from the high voltage output through a voltage divider, and is used as the regulation control input. When the voltage at the FB pin is slightly above 1.22V, comparator X1 disables most of the internal circuitry. Current is then provided by capacitor C2, which slowly discharges until the voltage at the FB pin drops below the lower hysteresis point of X1, about 6mV. X1 then enables the internal circuitry, turns on chip power, and the current in the inductor begins to ramp up. When the current through the driver transistor reaches about 450mA, comparator X2 clears the latch, which turns off the driver transistor for a preset 250nS. At the instant of shutoff, inductor current is diverted to the output through diode D1. During this 250nS time limit, inductor current decreases while its energy charges C2.

At the end of the 250ns time period, driver transistor is again allowed to turn on which ramps the current back up to the 450mA level. Comparator X2 clears the latch, it’s output turns off the driver transistor, and this allows delivery of L1’s stored kinetic energy to C2. This switching action continues until the output capacitor voltage is charged to the point where FB is at band gap (1.22V). When this condition is reached, X1 turns off the internal circuitry and the cycle repeats.
PERFORMANCE CHARACTERISTICS

Refer to the typical application circuit, $T_{AMB} = 25^\circ C$, unless otherwise specified.

Inductor Selection

For SP6691, the internal switch will be turned off only after the inductor current reaches the typical dc current limit ($I_{LIM}=450mA$). However, there is typically propagation delay of 200nS between the time when the current limit is reached and when the switch is actually turned off. During this 200nS delay, the peak inductor current will increase, exceeding the current limit by a small amount. The peak inductor current can be estimated by:

$$I_{PK} = I_{LIM} + \frac{V_{IN(MAX)}}{L} \cdot 200nS$$

The larger the input voltage and the lower the inductor value, the greater the peak current.

In selecting an inductor, the saturation current specified for the inductor needs to be greater than the SP6691 peak current to avoid saturating the inductor, which would result in a loss in efficiency and could damage the inductor.

Choosing an inductor with low DCR decreases power losses and increase efficiency.

Refer to Table 1 for some suggested low ESR inductors.

Diode Selection

A schottky diode with a low forward drop and fast switching speed is ideally used here to achieve high efficiency. In selecting a Schottky diode, the current rating of the schottky diode should be larger than the peak inductor current. Moreover, the reverse breakdown voltage of the schottky diode should be larger than the output voltage.

Capacitor Selection

Ceramic capacitors are recommended for their inherently low ESR, which will help produce low peak to peak output ripple, and reduce high frequency spikes.

For the typical application, 4.7µF input capacitor and 2.2µF output capacitor are sufficient. The input and output ripple could be further reduced by increasing the value of the input and output capacitors. Place all the capacitors as close to the SP6691 as possible for layout. For use as a voltage source, to reduce the output ripple, a small feedforward (47pF) across the top feedback resistor can be used to provide sufficient overdrive for the error comparator, thus reduce the output ripple.

Refer to Table 2 for some suggested low ESR capacitors.

LED Current Program

In the white LEDs application, the SP6691 is generally programmed as a current source. The bias resistor $R_b$, as shown in the typical application circuit is used to set the operating current of the white LED using the equation:

$$R_b = \frac{V_{FB}}{I_F}$$

where $V_{FB}$ is the feedback pin voltage (1.22V), $I_F$ is the operating current of the White LEDs. In order to achieve accurate LED current, 1%
precision resistors are recommended. Table 3 below shows the $R_b$ selection for different white LED currents. For example, to set the operating current to be 20mA, $R_b$ is selected as 60.4 Ω, as shown in the schematic.

Output Voltage Program

The SP6691 can be programmed as either a voltage source or a current source. To program the SP6691 as voltage source, the SP6691 requires 2 feedback resistors $R_1$ & $R_2$ to control the output voltage. As shown in Figure 22.

The formula and table for the resistor selection are shown below:

$$R_1 = \left(\frac{V_{OUT}}{1.22} - 1\right) \cdot R_2$$

Brightness Control

Dimming control can be achieved by applying a PWM control signal to the SHDN pin. The brightness of the white LEDs is controlled by increasing and decreasing the duty cycle of the PWM signal. A 0% duty cycle corresponds to zero LED current and a 100% duty cycle corresponds to full load current. While the operating frequency range of the PWM control is from 60Hz to 700Hz, the recommended maximum brightness frequency range of the PWM signal is from 60Hz to 200Hz. A repetition rate of at least 60Hz is required to prevent flicker. The magnitude of the PWM signal should be higher than the minimum SHDN voltage high.

Open Circuit Protection

When any white LED inside the white LED module fails or the LED module is disconnected from the circuit, the output and the feedback control will be open, thus resulting in a high output voltage, which may cause the SW pin voltage to exceed it maximum rating. In this case, a zener diode can be used at the output to limit the voltage on the SW pin and protect the part. The zener voltage should be larger than the maximum forward voltage of the White LED module.
Layout Consideration

Both the input capacitor and the output capacitor should be placed as close as possible to the IC. This can reduce the copper trace resistance which directly affects the input and output ripples. The feedback resistor network should be kept close to the FB pin to minimize copper trace connections that can inject noise into the system. The ground connection for the feedback resistor network should connect directly to the GND pin or to an analog ground plane that is tied directly to the GND pin. The inductor and the schottky diode should be placed as close as possible to the switch pin to minimize the noise coupling to the other circuits, especially the feedback network.

Power Efficiency

For the typical application circuit, the output efficiency of the circuit is expressed by

\[ \eta = \frac{V_{OUT} \cdot I_{OUT}}{V_{IN} \cdot I_{IN}} \]

Where \( V_{IN} \), \( I_{IN} \), \( V_{OUT} \), \( I_{OUT} \) are the input and output voltage and current respectively.

While the white LED efficiency is expressed by

\[ \eta = \frac{(V_{OUT} - 1.22) \cdot I_{OUT}}{V_{IN} \cdot I_{IN}} \]

This equation indicates that the white LED efficiency will be much smaller than the output efficiency of the circuit when \( V_{OUT} \) is not very large, compared to the feedback voltage (1.22V).

The other power is consumed by the bias resistor. To reduce this power loss, two circuits can be used, as shown in Figure 23 and Figure 24. In Figure 23, a general-purpose diode (for example, 1N4148) is used to bring the voltage across the bias resistor to be around 0.7V. \( R_1 \) is used to create a loop that provides around 100\( \mu \)A operating current for the diode. 3% efficiency improvement can be achieved by using this method.

To further improve the efficiency and reduce the effects of the ambient temperature on the diode D1 used in method 1, an op amp circuit can be used as shown in Figure 24. The gain of the op amp circuit can be calculated by:

\[ A_v = \frac{R_1 + R_2}{R_1} \]

If the voltage across the bias resistor is set to be 0.1V the current through \( R_1 \) and \( R_2 \) to be around 100\( \mu \)A, \( R_1 \) and \( R_2 \) can be selected as 1K and 11.2K respectively. LMV341 can be used because of its small supply current, offset voltage and minimum supply voltage. By using this method, the efficiency can be increased around 7%.
